

NON-KÄHLER EXPANDING RICCI SOLITONS

ANDREW S. DANCER AND MCKENZIE Y. WANG

ABSTRACT. We produce new examples of non-Kähler complete expanding gradient Ricci solitons on trivial vector bundles over a product of Einstein manifolds with positive scalar curvature.

Mathematics Subject Classification (2000): 53C25, 53C44

0. Introduction

A Ricci soliton consists of a complete Riemannian metric g and a complete vector field X on a manifold which give a solution to the equation:

$$(0.1) \quad \text{Ric}(g) + \frac{1}{2} \mathcal{L}_X g + \frac{\epsilon}{2} g = 0$$

where ϵ is a real constant and $\mathcal{L}$ denotes the Lie derivative. The soliton is called *steady* if $\epsilon = 0$, *expanding* if $\epsilon > 0$, and *shrinking* if $\epsilon < 0$. If X is a Killing field (including the case $X = 0$), g is then Einstein. Such a soliton is called *trivial*. Our main focus in this paper will be on nontrivial solitons.

Most of the known examples of nontrivial Ricci solitons are Kähler, e.g., [Ko], [Ca], [ChV], [Gu], [PTV], [FIK], [WZ], [PS], [ACGT], [DW1], [Ya]. In [DW2] we produced a family of non-Kähler steady solitons generalising examples of Bryant and Ivey [Bry], [Iv].

In this article we produce expanding analogues of the examples in [DW2]; as in that paper our examples are warped products (over an interval) with an arbitrary number r of factors. In fact the underlying manifolds are the same as in the steady case: trivial vector bundles over a product of Einstein manifolds with positive scalar curvature. Since one can easily arrange for the dimensions of the total spaces of the vector bundles to be odd, our solitons will in general not be Kähler. Regarding earlier work, for $r = 1$, a discussion can be found in §5, Chapter 1 of [Cetc]. The case $r = 2$ has been studied by Gastel and Kronz [GK] using somewhat different methods (related to those of C. Böhm [B] in the Einstein case (cf Remark 4.21)).

As is true for most known examples, the above solitons are of *gradient type*, that is, we have $X = \text{grad } u$ for a smooth function u . Equation (0.1) then becomes

$$(0.2) \quad \text{Ric}(g) + \text{Hess}(u) + \frac{\epsilon}{2} g = 0.$$

As in the steady case, we produce our examples by analysing a reduction of this equation to a system of ordinary differential equations. The main difference between the steady and expanding cases is that the Lyapunov function in the steady situation is no longer one in the expanding case. Consequently, additional careful analysis of the behaviour of the solution trajectories at the infinite end is necessary. In particular, we need to use the theory of centre manifolds in studying their ω -limit sets.

Finally we note that there are numerous homogeneous expanding solitons of non-gradient type on nilpotent Lie groups, as a result of the work of Lauret [La] and others. Our examples, however, will in general be inhomogeneous.

Date: revised November 26, 2008.

1. Multiple warped products

We consider multiple warped products, that is, metrics of the form

$$(1.1) \quad dt^2 + \sum_{i=1}^r g_i^2(t) h_i$$

on $I \times M_1 \times \dots \times M_r$ where I is an interval in $\mathbb{R}$ and (M_i, h_i) are Einstein manifolds with positive Einstein constants λ_i . We let d_i denote the (real) dimension of M_i and $n = d_1 + \dots + d_r$.

Moreover, the soliton potential u is taken to be a function of t alone.

The shape operator and Ricci endomorphism on the hypersurfaces of constant t are now given by

$$\begin{aligned} L_t &= \text{diag} \left(\frac{\dot{g}_1}{g_1} \mathbb{I}_{d_1}, \dots, \frac{\dot{g}_r}{g_r} \mathbb{I}_{d_r} \right) \\ \text{Ric}_t^\# &= \text{diag} \left(\frac{\lambda_1}{g_1^2} \mathbb{I}_{d_1}, \dots, \frac{\lambda_r}{g_r^2} \mathbb{I}_{d_r} \right) \end{aligned}$$

where $\mathbb{I}_m$ denotes the identity matrix of size m .

Motivated by [Cetc], we introduce new variables

$$(1.2) \quad X_i = \frac{\sqrt{d_i}}{(-\dot{u} + \text{tr} L)} \frac{\dot{g}_i}{g_i},$$

$$(1.3) \quad Y_i = \frac{\sqrt{d_i \lambda_i}}{g_i} \frac{1}{(-\dot{u} + \text{tr} L)},$$

for $i = 1, \dots, r$, and

$$(1.4) \quad W = \frac{1}{-\dot{u} + \text{tr} L}.$$

It is also convenient to introduce a new independent variable s defined by

$$(1.5) \quad \frac{d}{ds} := W \frac{d}{dt} = \frac{1}{(-\dot{u} + \text{tr} L)} \frac{d}{dt}.$$

We use a prime $'$ to denote differentiation with respect to s .

In these variables the Ricci soliton system becomes the following equations

$$(1.6) \quad X_i' = X_i \left(\sum_{j=1}^r X_j^2 - 1 \right) + \frac{Y_i^2}{\sqrt{d_i}} + \frac{\epsilon}{2} (\sqrt{d_i} - X_i) W^2,$$

$$(1.7) \quad Y_i' = Y_i \left(\sum_{j=1}^r X_j^2 - \frac{X_i}{\sqrt{d_i}} - \frac{\epsilon}{2} W^2 \right),$$

$$(1.8) \quad W' = W \left(\sum_{j=1}^r X_j^2 - \frac{\epsilon}{2} W^2 \right)$$

for $i = 1, \dots, r$. The constant ϵ above is taken to be positive as we are dealing with the case of expanding solitons. Note that the system is invariant under the transformations $Y_i \mapsto -Y_i$ or $W \mapsto -W$.

Conversely, if we have a solution of the above system, we may recover t and the g_i from

$$(1.9) \quad dt = W ds, \quad g_i = W \frac{\sqrt{d_i \lambda_i}}{Y_i}$$

The soliton potential u is recovered from integrating

$$(1.10) \quad \dot{u} = \text{tr}(L) - \frac{1}{W},$$

where $\text{tr}(L)$ is calculated using

$$(1.11) \quad \frac{\dot{g}_i}{g_i} = W^{-1} \frac{X_i}{\sqrt{d_i}}.$$

As in the steady case the equations admit a conservation law

$$(1.12) \quad \mathcal{L} - \epsilon \left(u - \frac{(n-1)}{2} \right) W^2 = CW^2$$

where C is a constant and $\mathcal{L} = \sum_{j=1}^r (X_j^2 + Y_j^2) - 1$. In fact we showed in [DW1] (cf Remark 2.8) and §1 of [DW2] that this is a general feature of gradient Ricci soliton equations of cohomogeneity one type.

2. Trajectories of the equations

A non-Einstein expanding soliton cannot be compact [Per], so, as in the steady case [DW2], we shall construct complete non-compact soliton metrics where there is a smooth collapse at one end onto a lower-dimensional submanifold. This can be achieved if we take one factor, say M_1 , to be a sphere S^{d_1} , so the submanifold is then $M_2 \times \cdots \times M_r$. We can take the end to correspond to $t = 0$ without any loss of generality. With the normalization $\lambda_1 = d_1 - 1$, the boundary conditions for the soliton solution to be C^2 are the existence of the following limits:

$$(2.1) \quad g_1(0) = 0 \quad : \quad g_i(0) = l_i \neq 0 \quad (i > 1),$$

$$(2.2) \quad \dot{g}_1(0) = 1 \quad : \quad \dot{g}_i(0) = 0 \quad (i > 1),$$

$$(2.3) \quad \ddot{g}_1(0) = 0 \quad : \quad \ddot{g}_i(0) \text{ finite} \quad (i > 1),$$

$$(2.4) \quad u(0), \dot{u}(0) = 0, \ddot{u}(0) \text{ finite}.$$

The regularity arguments of [DW2] show that, if in addition the third derivatives of g_i tend to finite limits at $t = 0$, the soliton is in fact smooth.

With the above remarks in mind, we consider trajectories emanating from the critical point of (1.6)-(1.8) given by

$$(2.5) \quad W = 0, X_1 = \beta, Y_1 = \hat{\beta}, X_i = Y_i = 0 \quad (i > 1)$$

where $\beta = \frac{1}{\sqrt{d_1}}$ and $\hat{\beta} = +\sqrt{1 - \beta^2}$. This critical point lies on the unit sphere in XY -space.

Remark 2.6. One can show that in the expanding case the only critical points of the flow that do *not* lie on the unit sphere in XY -space with $W = 0$ are

- (i) the origin $O := (W, X, Y) = (0, 0, 0)$,
- (ii) the points $E_{\pm} := (W, X_i, Y_i) = (\pm \sqrt{\frac{2}{n\epsilon}}, \frac{\sqrt{d_i}}{n}, 0)$ where $n = \sum_{j=1}^r d_j$.

We return now to the critical point (2.5). Linearising about this point gives a system whose matrix has a 2×2 block

$$\begin{pmatrix} 3\beta^2 - 1 & 2\beta\hat{\beta} \\ \beta\hat{\beta} & 0 \end{pmatrix}$$

corresponding to X_1, Y_1 : the remaining entries are diagonal, with β^2 and $\beta^2 - 1$ occurring r and $r - 1$ times respectively. (The extra β^2 term comes from the diagonal W entry in the matrix.)

The eigenvalues are therefore β^2 (r times), $\beta^2 - 1$ (r times), and $2\beta^2$. When $d_1 > 1$ the critical point is hyperbolic. We will assume this for the remainder of the paper.

We will parametrise trajectories emanating from this critical point so that the critical point corresponds to $s = -\infty$.

We see there is an r -parameter family of trajectories lying in the unstable manifold of this critical point and not lying in the unit sphere in XY -space.

The equation (1.7) for Y_i shows that Y_i is never zero unless it is identically zero. We note for future reference that the sets $\{Y_i = 0\}$ are closed invariant subsets of the flow. Also the system (1.6)-(1.8) and our initial conditions are invariant under the symmetries $Y_i \mapsto -Y_i$ for $i > 1$. Hence we may take Y_i to be everywhere positive for $i > 1$. Since $\lim_{s \rightarrow -\infty} Y_1 = \hat{\beta} > 0$ we may assume that $Y_1 > 0$ as well.

Similarly, the equation for W shows that W is either never zero or identically zero. (Again, this means that $\{W = 0\}$ is a flow invariant subset.) Now the conservation law (1.12) shows the latter cannot happen unless the trajectory is contained in the unit sphere $\sum_{j=1}^r (X_j^2 + Y_j^2) = 1$ and we are back in the Ricci flat case. Having chosen W to be nonzero, the symmetry of our equations under $W \mapsto -W$ implies that we can take W positive for all time.

Lemma 2.7. *The variables X_i are positive for all finite values of s .*

Proof. In Eqn (1.6) the coefficient of X_i is negative for large negative s , say for $s \leq s^*$. (In fact, it tends to $\beta^2 - 1 = \frac{1}{d_1} - 1$.) If X_i is non-positive at some $s_0 \leq s^*$, the equation (1.6) shows that $X'_i(s_0)$ is positive, hence these inequalities hold on $(-\infty, s_0]$ and X_i is negative and bounded away from zero as s tends to $-\infty$, a contradiction to our choice of critical point.

Hence X_i is positive on $(-\infty, s^*]$. But (1.6) shows that X'_i is positive if X_i vanishes, so in fact X_i stays positive for all time. $\square$

The following equations are easily deduced from (1.6)-(1.8):

Lemma 2.8. *We have the equations:*

$$(2.9) \quad \left(\frac{W}{Y_i}\right)' = \frac{X_i}{\sqrt{d_i}} \left(\frac{W}{Y_i}\right),$$

$$(2.10) \quad \left(\frac{X_i}{Y_i^2}\right)' = \frac{X_i}{Y_i^2} \left(-1 - \sum_{j=1}^r X_j^2 + \frac{2X_i}{\sqrt{d_i}} + \frac{\epsilon}{2} W^2\right) + \frac{1}{\sqrt{d_i}} + \frac{\epsilon \sqrt{d_i}}{2} \frac{W^2}{Y_i^2}.$$

Eqn.(2.9) now gives the following result.

Corollary 2.11. *For each i , the function $\frac{W}{Y_i}$ is monotonic increasing: so there exist $\mu_i \in [0, \infty)$ and $\sigma_i \in (0, \infty]$ such that $\lim_{s \rightarrow -\infty} \frac{W}{Y_i} = \mu_i$ and $\lim_{s \rightarrow \infty} \frac{W}{Y_i} = \sigma_i$. $\square$*

Remark 2.12. Note that $\mu_i = \lim_{t \rightarrow 0} \frac{g_i}{\sqrt{d_i \lambda_i}}$ by (1.3) and we shall show in Prop 4.7 that $\mu_i > 0$ if $i > 1$. Of course $\mu_1 = 0$.

3. Long-time behaviour of the flow

We recall from [DW2] the following quantities (the first of which has been referred to already in the discussion of the conservation law at the end of §1):

$$(3.1) \quad \mathcal{L} = \sum_{i=1}^r (X_i^2 + Y_i^2) - 1,$$

$$(3.2) \quad \mathcal{H} = \sum_{i=1}^r \sqrt{d_i} X_i.$$

It is also convenient to consider

$$(3.3) \quad \mathcal{Q} = \mathcal{L} + \frac{\epsilon}{2}(n-1)W^2.$$

Note that, in view of our initial conditions, we have $\mathcal{L}, \mathcal{Q} \rightarrow 0$ and $\mathcal{H} \rightarrow 1$ as $s \rightarrow -\infty$.

Recall that in the steady ($\epsilon = 0$) case, $\mathcal{L}$ was a Lyapunov function, since it had the same sign as its derivative. In the current expanding case this need no longer be true.

In fact we can calculate that our quantities satisfy the equations

$$(3.4) \quad \mathcal{L}' = 2\mathcal{L} \left(\sum_{i=1}^r X_i^2 - \frac{\epsilon}{2}W^2 \right) + \epsilon W^2 (\mathcal{H} - 1),$$

$$(3.5) \quad (\mathcal{H} - 1)' = \left(\sum_{j=1}^r X_j^2 - 1 - \frac{\epsilon}{2}W^2 \right) (\mathcal{H} - 1) + \mathcal{Q},$$

$$(3.6) \quad \mathcal{Q}' = \epsilon W^2 (\mathcal{H} - 1) + 2 \left(\sum_{j=1}^r X_j^2 - \frac{\epsilon}{2}W^2 \right) \mathcal{Q}.$$

We have, therefore, equations of the form

$$(3.7) \quad (\mathcal{H} - 1)' = f_1(\mathcal{H} - 1) + f_2 \mathcal{Q}$$

$$(3.8) \quad \mathcal{Q}' = f_3(\mathcal{H} - 1) + f_4 \mathcal{Q},$$

where (for finite values of s) the f_i are real analytic and f_2 and f_3 are positive.

Repeated differentiation of this system shows that if $\mathcal{H} - 1$ and $\mathcal{Q}$ both vanish at some s_0 , then they vanish there to all orders and hence are identically zero. These equations further imply that if $\mathcal{H} = 1$ and $\mathcal{Q} < 0$ at s_0 then $\mathcal{H}'(s_0) < 0$, while if $\mathcal{Q} = 0$ and $\mathcal{H} < 1$ at s_0 , then $\mathcal{Q}'(s_0) < 0$.

Proposition 3.9. *If $\mathcal{H} < 1$ and $\mathcal{Q} < 0$ for large negative s , then these inequalities hold for all finite s .*

Proof. If the inequalities do not hold for all time, consider the first point s_0 at which one fails. This leads to one of the three possibilities above, all of which give a contradiction. $\square$

Next we note that $\mathcal{Q} < 0$ for all $s \leq s^*$ implies that $\mathcal{H} < 1$ for all $s \leq s^*$. Indeed if we substitute our conservation law (1.12) into the above equation for $\mathcal{H}'$ and simplify, we obtain

$$\mathcal{H}' = (1 - \mathcal{H}) \left(\sum_{i=1}^r Y_i^2 + \frac{\epsilon}{2}nW^2 \right) + \mathcal{H}W^2(C + \epsilon u).$$

But in terms of $\mathcal{Q}$, the conservation law is

$$\mathcal{Q} = W^2(C + \epsilon u).$$

So if at some $s_0 \leq s^*$ we have $\mathcal{H} \geq 1$, then $\mathcal{H}$ would be monotone decreasing to the left of s_0 , contradicting $\lim_{s \rightarrow -\infty} \mathcal{H} = 1$.

Proposition 3.10. *There is an r -parameter family of our trajectories with $\mathcal{H} < 1$ and $\mathcal{Q} < 0$ for all finite s .*

Proof. In view of Prop 3.9 and the ensuing discussion, it suffices to observe that there is an r -parameter family of initial directions at our critical point (2.5) along which $\mathcal{Q}$ is strictly decreasing. These are given by tangent vectors to the unstable manifold which have a negative inner product with the eigenvector $(0, 2\beta, 0, \dots, 0, \hat{\beta}, 0, \dots, 0)$ of the linearization (associated to the eigenvalue $2\beta^2$). $\square$

Corollary 3.11. *We have*

- (1) $\mathcal{L} < 0$ for all finite s , so the trajectory stays in the region $\sum_{j=1}^r (X_j^2 + Y_j^2) < 1$.
- (2) $W < \sqrt{\frac{2}{\epsilon}}$ for all finite s .
- (3) All variables W, X_i, Y_i are bounded so the flow exists for $s \in (-\infty, \infty)$.

Proof. Now (1) follows from Prop 3.10 since $\mathcal{L} < \mathcal{Q}$. If $W \geq \sqrt{\frac{2}{\epsilon}}$ at some s_0 , then Eqn.(1.8) implies that $W'(s_0) < 0$. Hence W is monotone decreasing to the left of s_0 , contradicting $\lim_{s \rightarrow -\infty} W = 0$. This proves (2), and (3) follows immediately. We note that a better upper bound for X_i follows from using $\mathcal{H} < 1$. $\square$

Remark 3.12. It follows from equations (3.7)-(3.8) that the $2r - 1$ -dimensional submanifold $\mathcal{S}$ of phase space defined by $\mathcal{H} = 1, \mathcal{Q} = 0$ is invariant under the flow. As

$$u' = W\dot{u} = W \operatorname{tr}(L) - 1 = \sum_{i=1}^r \sqrt{d_i} X_i - 1 = \mathcal{H} - 1$$

we see that trajectories in $\mathcal{S}$ give Ricci solitons with constant potential u , that is, Einstein metrics.

We now return to the trajectories of Proposition 3.10, and in particular to the analysis of their long-time behaviour. Let γ denote such a trajectory (with W, Y_i positive).

Recall that the ω -limit set of the trajectory γ is the set

$$\Omega = \{(W^*, X^*, Y^*) : \exists s_n \rightarrow +\infty \text{ with } \gamma(s_n) = (W(s_n), X(s_n), Y(s_n)) \rightarrow (W^*, X^*, Y^*)\}.$$

As our trajectory actually lies in a compact set, we know ([Pk] §3.2) that Ω is a compact, connected, non-empty set that is invariant under the flow of our equations (both forwards and backwards). Moreover, by Cor. 2.11, Ω is contained in the set

$$\left\{ \frac{W}{Y_i} = \sigma_i, \quad i = 1, \dots, r \right\}.$$

If $\sigma_i = +\infty$, this condition is equivalent (since W is bounded) to $Y_i = 0$. If σ_i is finite, then we claim that Ω still lies in $Y_i = 0$. To see this, note first that flow-invariance and (2.9) show that Ω is contained in $X_i = 0$. Now flow-invariance and Eqn.(1.6) show we must have $Y_i = W = 0$. We conclude that

$$\Omega \subset \bigcap_{i=1}^r \{(W, X, Y) : Y_i = 0\},$$

which is also a flow invariant set. As well, by Proposition 3.10, Lemma 2.7, and Corollary 3.11, we also have

$$(3.13) \quad \Omega \subset \left\{ 0 \leq X_i \ (1 \leq i \leq r), \ 0 \leq W \leq \sqrt{\frac{2}{\epsilon}}, \ \mathcal{H} \leq 1, \ \mathcal{Q} \leq 0, \right\}.$$

Remark 3.14. We shall see in Lemma 3.29 that σ_i is always infinite.

We will now show that Ω contains the origin, and from this, with some more work, deduce the convergence of the trajectory γ to the origin. To this end we will consider the flow restricted to Ω .

Proposition 3.15. *If Ω contains a point with zero W -coordinate, then Ω contains the origin.*

Proof. If Ω contains a point p whose W -coordinate is zero, let ϕ denote its trajectory. Then along it, we have $W = 0$ and (from above) $Y_i = 0$. Now the X_i evolve by

$$X'_i = X_i \left(\sum_{k=1}^r X_k^2 - 1 \right).$$

This implies that $G := \sum_{k=1}^r X_k^2$ satisfies the equation

$$G' = 2G(G - 1).$$

Moreover $G \leq 1$ since $\mathcal{Q} \leq 0$. If $G \equiv 0$, then p is the origin. If G is not identically 1, then upon integrating the equation we see that ϕ flows into the origin. Hence Ω , being closed and flow invariant, must contain the origin. If $G \equiv 1$, then p is a critical point of our vector field lying on the unit sphere in XY space (cf Remark 2.6). We will show by examining the linearisation of (1.6)-(1.8) at p that any trajectory (which is not a critical point) must leave any small neighbourhood of p in finite time and cannot return. This contradicts $p \in \Omega$.

Let $p = (0, p_1, \dots, p_r, 0, \dots, 0)$ with $\sum_{i=1}^r p_i^2 = 1$. Setting $X_i = x_i + p_i$, $Y_i = y_i$ and $W = w$, we have

$$\begin{aligned} x'_i &= 2p_i \sum_{j=1}^r p_j x_j + \dots \\ y'_i &= \left(1 - \frac{p_i}{\sqrt{d_i}}\right) y_i + \dots \\ w' &= w + \dots \end{aligned}$$

where $\dots$ denote terms of higher order. Hence the zero eigenspace of the linearisation coincides with the tangent space of the critical submanifold $\{W = 0, Y_i = 0 (1 \leq i \leq r), \sum_i X_i^2 = 1\}$ at p . The remaining eigenvalues of the linearisation are 2 (with eigenvector p), 1, and $1 - \frac{p_i}{\sqrt{d_i}} > 0, (1 \leq i \leq r)$. The stable manifold at p therefore reduces to a point and the zero eigenvalues correspond to directions tangent to the submanifold of fixed points of the flow. This proves our claim. $\square$

In view of the preceding result, we now consider the case when Ω does not contain any points with W -coordinate equal to 0. Since Ω is compact, the function W is bounded below by a positive constant w_0 on Ω . We again consider the trajectory ϕ of a point $p \in \Omega$ and denote by Ω_ϕ its ω -limit set. Note that $\Omega_\phi \subset \Omega$ (since Ω is closed and flow-invariant) and Ω_ϕ is also non-empty, compact, connected and flow-invariant. In analysing this set we may assume, by (1.6) and the fact that W is nonzero, that $X_i > 0, 1 \leq i \leq r$, along ϕ .

Letting $\tilde{X}_i = X_i / \sqrt{d_i}$, we have along ϕ

$$\left(\frac{\tilde{X}_i}{\tilde{X}_j} \right)' = \frac{\epsilon W^2}{2\tilde{X}_j} \left(1 - \frac{\tilde{X}_i}{\tilde{X}_j} \right),$$

where we have used the fact that $Y_i = 0, 1 \leq i \leq r$. Hence $\frac{\tilde{X}_i}{\tilde{X}_j}$ is either monotonic decreasing as $s \rightarrow +\infty$ to a limit $\lambda_{ij} \geq 1$, or monotonic increasing to a limit $\lambda_{ij} \leq 1$. (This includes the possibility that $\frac{\tilde{X}_i}{\tilde{X}_j}$ is identically 1.) Letting $\tau_{ij} = \frac{\sqrt{d_i}}{\sqrt{d_j}} \lambda_{ij}$, we see that (since X_j are bounded)

$$X_i - \tau_{ij} X_j = X_j \left(\frac{X_i}{X_j} - \tau_{ij} \right) \rightarrow 0 \text{ as } s \rightarrow +\infty.$$

Hence Ω_ϕ must lie in the subspace

$$\{X_i - \tau_{ij} X_j = 0, \quad 1 \leq i, j \leq r\}$$

for some constants τ_{ij} (depending on ϕ). As

$$(X_i - \tau_{ij}X_j)' = (X_i - \tau_{ij}X_j) \left(\sum_{k=1}^r X_k^2 - 1 - \frac{\epsilon}{2}W^2 \right) + \frac{\epsilon}{2}W^2(\sqrt{d_i} - \tau_{ij}\sqrt{d_j})$$

and $W > 0$, we must have $\tau_{ij} = \sqrt{d_i}/\sqrt{d_j}$, i.e., $\lambda_{ij} = 1$ for all i, j .

Therefore, Ω_ϕ is contained in a plane given by $X_i = \frac{\sqrt{d_i}X_1}{\sqrt{d_1}}$, $i = 2, \dots, r$. Parametrising this plane by X_1, W , we can write the flow as:

$$(3.16) \quad X_1' = X_1 \left(\frac{n}{d_1}X_1^2 - 1 \right) + \frac{\epsilon}{2}(\sqrt{d_1} - X_1)W^2$$

$$(3.17) \quad W' = W \left(\frac{n}{d_1}X_1^2 - \frac{\epsilon}{2}W^2 \right).$$

Note that in this 2-plane, we have $\mathcal{H} = \frac{n}{\sqrt{d_1}}X_1$, so the condition $\mathcal{H} \leq 1$ becomes $X_1 \leq \sqrt{d_1}/n$.

In view of (3.13) and the fact that on Ω we also have $W \geq w_0$ for some positive constant w_0 , we only need to focus on the flow in the rectangular box in the X_1W -plane given by

$$\mathcal{B} := \left\{ 0 \leq X_1 \leq \frac{\sqrt{d_1}}{n}, w_0 \leq W \leq \sqrt{\frac{2}{\epsilon}} \right\},$$

which contains Ω_ϕ . The only critical point of (3.16)-(3.17) lying in $\mathcal{B}$ is $(X_1, W) = (\frac{\sqrt{d_1}}{n}, \sqrt{\frac{2}{n\epsilon}})$, which lies on the edge of $\mathcal{B}$. (This corresponds, of course, to the critical point E_+ of the full system discussed in Remark 2.6, which lies in $\{\mathcal{H} = 1, \mathcal{Q} = 0\}$.)

Observe that above the line $X_1 = \sqrt{\frac{\epsilon d_1}{2n}}W$ in this region we have W strictly decreasing while below this line W strictly increases. On the line, W' is zero and $X_1' = X_1(-1 + \frac{nX_1}{\sqrt{d_1}})$ is negative. On $X_1 = 0$ we have X_1' positive, while on $X_1 = \sqrt{d_1}/n$ we have X_1' negative below the critical point E_+ and positive above it. One can also check that on the line $W = \sqrt{\frac{2}{\epsilon}}$ we have $X_1' > 0$ and $W' < 0$. On the line $W = w_0$, (for w_0 small), X_1' goes from positive to negative. As W increases from w_0 to $\sqrt{\frac{2}{n\epsilon}}$ the zero of X_1' moves to the right and tends to $\sqrt{d_1}/n$.

We deduce from the above picture that the only trajectory that starts in $\Omega_\phi \subset \mathcal{B}$ and remains in $\mathcal{B}$ must lie above the line $X_1 = \sqrt{\frac{\epsilon d_1}{2n}}W$ and must flow into E_+ . Indeed, if we linearise the flow in the plane about E_+ , we find that the eigenvalues of the linearised operator are $\frac{1}{2}(-1 \pm \sqrt{1 + (8/n)})$, so that E_+ is a hyperbolic critical point. Since Ω_ϕ is connected and flow-invariant, we conclude that Ω_ϕ consists of a trajectory which ultimately coincides with the part of the stable manifold (curve) at E_+ lying in $\mathcal{B}$. In particular, there must be a sequence of points on our first trajectory γ which lie arbitrarily close to this portion of the stable curve.

Next recall that Ω , and hence Ω_ϕ , are contained in $\{\mathcal{Q} \leq 0\}$. The intersection of the quadric $\mathcal{Q} = 0$ and our 2-plane is the ellipse $\frac{nX_1^2}{d_1} + \frac{\epsilon}{2}(n-1)W^2 = 1$. E_+ lies on this ellipse and we may take $\nabla Q|_{E_+} = (\frac{2}{\sqrt{d_1}}, (n-1)\sqrt{\frac{2\epsilon}{n}})$ as a normal vector to the quadric at E_+ . A tangent vector to the stable curve which points out of the region $\mathcal{B}$ is $\xi := (\sqrt{\frac{2d_1\epsilon}{n}}, \frac{n}{n-1}(\frac{1}{2} - \frac{1}{2}\sqrt{1 + \frac{8}{n} - \frac{2}{n}}))$. One can now check that $\nabla Q|_{E_+} \cdot \xi < 0$. Hence the stable curve and the quadric $\mathcal{Q} = 0$ lie on opposite sides of the tangent space at E_+ to the quadric. This contradicts the last statement of the previous paragraph unless $\Omega_\phi = \{E_+\}$ for every trajectory ϕ in Ω .

We have shown:

Proposition 3.18. *Suppose that all points of Ω have nonzero W -coordinate. Then for each point $p \in \Omega$, the ω -limit set Ω_ϕ of the trajectory ϕ through p is the singleton set $\{E_+\}$. $\square$*

Lemma 3.19. *A trajectory of the full system (1.6)-(1.8) lying in a compact set and having ω -limit set $\{E_+\}$ must converge to E_+ . Moreover, either it lies entirely in the invariant submanifold $\mathcal{S} := \{\mathcal{Q} = 0, \mathcal{H} = 1\}$ or it eventually lies (for finite values of s) in $\{\mathcal{Q} < 0, \mathcal{H} > 1\}$ or $\{\mathcal{Q} > 0, \mathcal{H} < 1\}$.*

Proof. Let Γ denote such a trajectory. Convergence follows because otherwise one can find $s_n \rightarrow +\infty$ with $\Gamma(s_n)$ lying outside some open ball around E_+ . But a subsequence of $\Gamma(s_n)$ would then converge to a point in the ω -limit set distinct from E_+ , a contradiction.

Consider the linearisation at E_+ of the full system (1.6)-(1.8). One finds that the linearised operator has only one positive eigenvalue $\frac{1}{2}(-1 + \sqrt{1 + \frac{8}{n}})$; the remaining eigenvalues are $-1/n$ (r times), -1 ($r - 1$ times) and $\frac{1}{2}(-1 - \sqrt{1 + \frac{8}{n}})$. Furthermore, the $-1/n$ eigenspace consists of vectors of the form $(W, X, Y) = (0, 0, Y)$ while the -1 eigenspace consists of vectors of the form $(W, X, Y) = (0, \xi, 0)$ where ξ is orthogonal to $\eta := (\sqrt{d_1}, \dots, \sqrt{d_r})$. An eigenvector for the remaining negative eigenvalue is $v := (\frac{n}{n-1}(\frac{1}{2}(-1 + \sqrt{1 + \frac{8}{n}}) + \frac{2}{n}), -\sqrt{\frac{2\epsilon}{n}}\eta, 0)$.

Notice that except for v , the rest of the eigenvectors with negative eigenvalues are orthogonal to $\nabla \mathcal{Q}$ and $\nabla \mathcal{H}$ at E_+ . So they actually span the tangent space at E_+ to $\mathcal{S}$. (In particular, for the restricted flow on $\mathcal{S}$ the point E_+ is actually a sink.) One checks that $v \cdot \nabla \mathcal{Q} > 0$ and $v \cdot \nabla \mathcal{H} < 0$ at E_+ . Now our trajectory Γ must ultimately lie in the stable manifold of E_+ , so any trajectory in the stable manifold at E_+ which does not lie in $\{\mathcal{H} = 1, \mathcal{Q} = 0\}$ must lie in $\{\mathcal{Q} < 0, \mathcal{H} > 1\}$ or $\{\mathcal{Q} > 0, \mathcal{H} < 1\}$. $\square$

Corollary 3.20. *Suppose that all points of Ω have nonzero W -coordinate. Then Ω is a union of trajectories lying in the intersection of the invariant submanifold $\mathcal{S} := \{\mathcal{Q} = 0, \mathcal{H} = 1\}$ with the invariant set $\{Y = 0\}$. $\square$*

We shall denote the invariant set $\{\mathcal{Q} = 0, \mathcal{H} = 1, Y = 0\}$ by $\hat{\mathcal{S}}$. Note that $\hat{\mathcal{S}}$, like $\mathcal{S}$, is compact because of the condition $\mathcal{Q} = 0$.

We may now observe that on the set $\{\mathcal{H} = 1, Y = 0\}$ the quantities $G := \sum_{j=1}^r X_j^2$ and $J = G - \frac{\epsilon}{2}W^2$ satisfy

$$G' = 2(G - 1)J$$

and

$$(3.21) \quad J' = 2J(J - 1).$$

Moreover, if we in addition impose the condition $\mathcal{Q} = 0$, then we may rewrite J as $J = \frac{nG-1}{n-1}$. The Cauchy-Schwartz inequality applied to the condition $\mathcal{H} := \sum_{i=1}^r \sqrt{d_i}X_i = 1$ shows that $G \geq \frac{1}{n}$ on $\mathcal{H} = 1$, with equality if and only if $X_i = \frac{\sqrt{d_i}}{n}$ for all i . Furthermore, the condition $\mathcal{Q} = 0$ implies that $\mathcal{L} \leq 0$ and hence $G \leq 1$.

Hence we find that on the set $\hat{\mathcal{S}}$ the function J satisfies $0 \leq J \leq 1$, with $J = 0$ only at the points $E_\pm$ given by $(W, X, Y) = (\pm\sqrt{\frac{2}{\epsilon n}}, \frac{\sqrt{d_1}}{n}, \dots, \frac{\sqrt{d_r}}{n}, 0, \dots)$, and $J = 1$ only at the points with $Y = W = 0$ and $\sum_{j=1}^r X_j^2 = 1$. Note that these latter points are the critical points of the flow discussed in the proof of Proposition 3.15.

It now follows from equation (3.21) that J is a Lyapunov function on $\hat{\mathcal{S}}$. Points on the plane $W = 0$ in $\hat{\mathcal{S}}$ have $J = 1$ and are fixed under the flow. Points in the regions $W > 0$ and $W < 0$ flow to the critical points E_+ and E_- respectively.

We can now deduce:

Proposition 3.22. *Let γ be one of the r -parameter family of trajectories with Y_i, W positive emanating from the critical point (2.5) and entering the region $\{Q < 0\}$. Then its ω -limit set Ω contains the origin.*

Proof. By Proposition 3.15 we just have to consider the case when Ω contains no point with zero W -coordinate. By Corollaries 3.20 and 3.13 we know that Ω is contained in the region of $\hat{\mathcal{S}}$ with $W > 0$. But it is also closed and invariant under forwards and backwards flows. Our discussion above shows that $\Omega = \{E_+\}$, as if it contained another point then the backwards trajectory would converge to a critical point with $W = 0$, which would thus have to lie in Ω .

So Ω consists of the critical point $\{E_+\}$. Now Lemma 3.19 shows that the bounds established in Proposition 3.10 are violated, so this case cannot occur. $\square$

Our next aim is to show that the trajectory γ actually converges to the origin.

The linearisation of our flow (1.6)-(1.8) about the origin is

$$\begin{aligned} X'_i &= -X_i, \\ Y'_i &= 0, \\ W' &= 0, \end{aligned}$$

so the 0-eigenspace is given by $X = 0$. Following Glendinning [Gl], for example, we seek a centre manifold with local expression in the form $X_i = h_i(Y, W)$, where we need h_i and Dh_i to vanish at the origin.

We write

$$X_i = \sum_{j,k} a_{jk}^{(i)} Y_j Y_k + \sum_j b_j^{(i)} Y_j W + c^{(i)} W^2 + \dots$$

where $\dots$ refers to terms of higher order than quadratic order. Now $X'_i = \sum_k \frac{\partial h_i}{\partial Y_k} Y'_k + \frac{\partial h_i}{\partial W} W'$, while X'_i can also be expressed using (1.6). Equating terms we find the quadratic terms in the expression for X_i are as follows:

$$X_i = \frac{1}{\sqrt{d_i}} Y_i^2 + \frac{\epsilon \sqrt{d_i}}{2} W^2 + \dots$$

So $Y'_i = Y_i(-\frac{1}{d_i} Y_i^2 - \epsilon W^2 + \dots)$ and $W' = -\frac{\epsilon}{2} W^3 + \dots$, where $\dots$ in the above refers to terms with total degree greater than those displayed.

It follows from this that

$$\left(\sum_{i=1}^r Y_i^2 + W^2 \right)' = -2 \left(\sum_{i=1}^r \frac{1}{d_i} Y_i^4 + \epsilon W^2 \sum_{i=1}^r Y_i^2 + \frac{\epsilon}{2} W^4 \right) + \text{higher order terms.}$$

In other words, $(\sum_{i=1}^r Y_i^2) + W^2$ is a Lyapunov function for the local dynamics of our centre manifold near the origin. Hence the origin is asymptotically stable, i.e., on the centre manifold the flow near the origin converges to the origin. Since the nonzero eigenvalues of the linearisation of the full system are negative, the centre manifold theorem yields

Proposition 3.23. *The origin is a sink for our flow.* $\square$

Combining Prop 3.23 with Prop 3.22 (which showed that the trajectory γ approaches the origin arbitrarily closely), we have

Theorem 3.24. *The trajectory γ converges to the origin as s tends to $+\infty$.* $\square$

The above theorem allows us to deduce information about the asymptotics of our metric once we derive the following limit; the proof is similar to that for Lemma 3.7 in [DW2].

Lemma 3.25. *We have $\lim_{s \rightarrow +\infty} \frac{X_i}{W^2} := \Lambda_i = \frac{1}{\sigma_i^2 \sqrt{d_i}} + \frac{\epsilon}{2} \sqrt{d_i}$.*

Proof. Observe that X_i/W^2 satisfies the differential equation

$$(3.26) \quad \left(\frac{X_i}{W^2} \right)' = \left(-1 - \sum_{j=1}^r X_j^2 \right) \frac{X_i}{W^2} + \frac{Y_i^2}{W^2 \sqrt{d_i}} + \frac{\epsilon}{2} (X_i + \sqrt{d_i})$$

By Theorem 3.24, the coefficient F_i of $\frac{X_i}{W^2}$ tends to -1 as $s \rightarrow +\infty$. The sum K_i of the remaining terms on the right hand side converges to Λ_i . In particular, if $\frac{X_i}{W^2}$ tends to a finite limit a , then its derivative tends to $-a + \Lambda_i$, so a must equal Λ_i .

Let $0 < \delta < \min(1, \Lambda_i)$, and pick $s^*(\delta)$ so that $\sum_{j=1}^r X_j^2$ is less than δ and $\Lambda_i - \delta < K_i < \Lambda_i + \delta$ for $s \geq s^*(\delta)$. It follows that if $\frac{X_i}{W^2}(s_0) \geq \frac{\Lambda_i + \delta}{1 - \delta}$ for some $s_0 > s^*(\delta)$, then $\left(\frac{X_i}{W^2} \right)' < 0$ at s_0 . Similarly, if $\frac{X_i}{W^2}(s_0) \leq \frac{\Lambda_i - \delta}{1 + \delta}$, then $\left(\frac{X_i}{W^2} \right)' > 0$ at s_0 . So if $\frac{X_i}{W^2}$ enters the horizontal strip $\frac{\Lambda_i - \delta}{1 + \delta} < y < \frac{\Lambda_i + \delta}{1 - \delta}$ at some $s > s^*(\delta)$, it is trapped there.

On the other hand, if $\frac{X_i}{W^2}$ never enters the strip for $s > s^*(\delta)$ then it is either monotonic increasing to some number less than or equal to $\frac{\Lambda_i - \delta}{1 + \delta} < \Lambda_i$, or monotonic decreasing to some number greater than or equal to $\frac{\Lambda_i + \delta}{1 - \delta} > \Lambda_i$. Both of these outcomes contradict the discussion in the first paragraph.

So $\frac{X_i}{W^2}$ is indeed trapped in the strip for large enough s . Since this conclusion holds for all δ , the result follows. $\square$

We therefore have an estimate

$$(3.27) \quad \sum_{k=1}^r X_k^2 \leq cW^4 \quad \text{for } s \text{ large}$$

where c is a positive constant. Hence, by (1.8), W is decreasing for sufficiently large s .

Lemma 3.28. *The metric corresponding to our trajectory is complete at $s = +\infty$.*

Proof. The geodesic distance to infinity is $\int_0^\infty W ds = \int_0^\infty \frac{dW}{\frac{\epsilon}{2}W^2 - \sum_{k=1}^r X_k^2}$, which is infinite $\square$

Lemma 3.29. *The quantities Λ_i equal $\frac{\epsilon\sqrt{d_i}}{2}$. Equivalently, the quantities $\sigma_i = \lim_{s \rightarrow +\infty} \frac{W}{Y_i}$ equal ∞ . Hence $\lim_{t \rightarrow +\infty} \frac{\dot{g}_i}{g_i W} = \frac{\epsilon}{2}$.*

Proof. By (1.7) and (1.8) we have

$$\frac{W'}{Y_i'} = \frac{W}{Y_i} \frac{(\sum_k X_k^2 - \frac{\epsilon}{2}W^2)}{(\sum_k X_k^2 - \frac{X_i}{\sqrt{d_i}} - \frac{\epsilon}{2}W^2)}.$$

The right-hand side tends to $\frac{\sigma_i \epsilon}{\epsilon + (2\Lambda_i/\sqrt{d_i})}$, and Λ_i is positive. But by L'Hôpital's rule, when the left-hand side tends to a limit this must be σ_i . So $\sigma_i \in (0, \infty]$ cannot be finite. The last assertion now follows immediately from (1.11). $\square$

In fact, (1.8) and the estimate (3.27) show that for any sufficiently small $\delta > 0$, there is some $\hat{s}$ and constants A_1 and A_2 such that on $[\hat{s}, +\infty)$ we have

$$\frac{1}{\epsilon s + A_1} \leq W^2 \leq \frac{1}{(\epsilon - 2\delta)s + A_2}.$$

As $dt = W ds$, we deduce $s \sim \frac{\epsilon t^2}{4}$ so $W \sim \frac{2}{\epsilon t}$. Integrating the relation $\frac{\dot{g}_i}{g_i} = \frac{1}{\sqrt{d_i}} \frac{X_i}{W}$ then shows that for all sufficiently small $\delta > 0$ there is some $\hat{t}$ and positive constants a_1, a_2 (depending on δ) satisfying $1 - \delta < \frac{a_2}{a_1} < 1$ such that on $[\hat{t}, +\infty)$ we have

$$(a_1(t - \hat{t}) + 1)^{1-\delta} < \frac{g_i(t)}{g_i(\hat{t})} < (a_2(t - \hat{t}) + 1)^{1+\delta}.$$

Remark 3.30. These estimates are consistent with our expectation that the metric has an asymptotically conical geometry. Asymptotically conical behaviour has also been observed for the known examples of Kählerian expanding Ricci solitons. By contrast, the known examples of steady solitons are usually asymptotic to a paraboloid or a circle bundle over a paraboloid.

4. The flow near the critical point

To check smoothness at the collapsing submanifold, we must now analyse the behaviour of our trajectory as s tends to $-\infty$. Recall that we have arranged for $X_1 \rightarrow \beta = \frac{1}{\sqrt{d_1}}$, $Y_1 \rightarrow +\sqrt{1-\beta^2}$, and the remaining variables to tend to 0. Most of the analysis below is analogous to that for the steady case with the role of $\sqrt{\mathcal{L}/C}$ now played by W .

We first recall the following useful lemma from [DW2].

Lemma 4.1. *Suppose a function F satisfies a differential equation*

$$(4.2) \quad F' = HF + K$$

where H, K are functions tending respectively to finite limits h, k as s tends to $-\infty$, where $h < 0$ and $k \neq 0$.

Then either $\lim_{s \rightarrow -\infty} F(s) = -\frac{k}{h}$ or F tends to ∞ or $-\infty$ as s tends to $-\infty$. Moreover in the case of infinite limit F is monotonic for sufficiently large negative s .

Lemma 4.3. *As $s \rightarrow -\infty$, X_i/Y_i^2 remains bounded.*

Proof. If $i = 1$ the claim follows immediately from our initial conditions.

Now let $i > 1$. Since $\lim_{s \rightarrow -\infty} (\sum_{j=1}^r X_j^2) = \beta^2$, $\lim_{s \rightarrow -\infty} X_i = 0 = \lim_{s \rightarrow -\infty} W$, and $\lim_{s \rightarrow -\infty} \frac{W}{Y_i} = \mu_i < \infty$, for any $0 < \delta < 1 - \beta^2$ we can find s^* so that for $s \leq s^*$ we have

$$\frac{Y_i^2}{\sqrt{d_i}} + \frac{\epsilon}{2}(\sqrt{d_i} - X_i)W^2 < \frac{Y_i^2}{\sqrt{d_i}} + \frac{\epsilon}{2}(\sqrt{d_i} + \delta)(\mu_i + \delta)^2 Y_i^2$$

and $Y_i' > 0$, and also $\sum_{j=1}^r X_j^2 - 1 < \beta^2 - 1 + \delta < 0$.

We claim that on $(-\infty, s^*]$ we must have

$$\frac{X_i}{Y_i^2} \leq \frac{\frac{1}{\sqrt{d_i}} + \frac{\epsilon}{2}(\sqrt{d_i} + \delta)(\mu_i + \delta)^2}{(1 - \beta^2 - \delta)}.$$

For if this fails at $s_0 \leq s^*$, then

$$X_i(s_0) \left(\sum_{j=1}^r X_j^2(s_0) - 1 \right) < \frac{\frac{1}{\sqrt{d_i}} + \frac{\epsilon}{2}(\sqrt{d_i} + \delta)(\mu_i + \delta)^2}{(1 - \beta^2 - \delta)} Y_i(s_0)^2 (\beta^2 - 1 + \delta).$$

Hence by (1.6) $X_i'(s_0) < 0$. Moreover, from above, $Y_i'(s_0) > 0$. So in fact our lower bound on X_i/Y_i^2 holds on the whole interval $(-\infty, s_0]$ and it follows that X_i is monotone decreasing on this interval. But this contradicts the fact that X_i tends to zero as s tends to $-\infty$ and our claim is established. $\square$

Lemma 4.4. *For $i > 1$ we have $\lim_{s \rightarrow -\infty} \frac{X_i}{Y_i^2} = \frac{\frac{1}{\sqrt{d_i}} + \frac{\epsilon}{2}\sqrt{d_i}\mu_i^2}{1+\beta^2}$. For $i = 1$, the corresponding limit is $\beta/(1 - \beta^2)$.*

Proof. The differential equation (2.10) is of the form (4.2), with $h = -(1+\beta^2)$ and $k = \frac{1}{\sqrt{d_i}} + \frac{\epsilon}{2}\sqrt{d_i}\mu_i^2$. The desired result now follows from Lemmas 4.1 and 4.3. $\square$

Proposition 4.5. *As t tends to 0 we have the following limiting values:*

$$g_1(0) = 0 \quad : \quad \dot{g}_1(0) = 1 \quad : \quad \dot{g}_i(0) = 0 \quad (i > 1).$$

Proof. The first limit follows from (1.9) and the fact that $\lim_{s \rightarrow -\infty} \frac{W}{Y_1} = 0$. Since

$$(4.6) \quad \dot{g}_i = \sqrt{\lambda_i}(X_i/Y_i),$$

the second limit follows from the initial values of X_1 and Y_1 (recall that $\lambda_1 = d_1 - 1$). The last limit follows from the above formula, Lemma 4.3 and $\lim_{s \rightarrow -\infty} Y_i = 0$ for $i > 1$. $\square$

Proposition 4.7. *For $i > 1$, $\mu_i := \lim_{s \rightarrow -\infty} \frac{W}{Y_i}$ and $g_i(0) = \sqrt{\lambda_i d_i} \mu_i$ are finite and positive.*

Proof. Finiteness follows from Cor (2.11); it remains to prove positivity. Using (4.6) and (1.7) we see that

$$\frac{g'_i}{g_i} = \frac{X_i}{\sqrt{d_i}} = \frac{1}{2\sqrt{d_i}} \frac{X_i}{Y_i^2} \frac{(Y_i^2)'}{\left(\sum_{j=1}^r X_j^2\right) - \frac{X_i}{\sqrt{d_i}} - \frac{\epsilon}{2} W^2}.$$

Integrating this over an interval (s, s^*) using the upper bound for X_i/Y_i^2 in the proof of Lemma 4.3 and the lower bound $\sum_{j=1}^r X_j^2 - \frac{X_i}{\sqrt{d_i}} - \frac{\epsilon}{2} W^2 > \beta^2 - \delta$ we get a bound

$$\frac{g_i(s^*)}{g_i(s)} \leq \exp(C_i(Y_i^2(s^*) - Y_i^2(s)))$$

where C_i is a positive constant. This gives the desired positive lower bound for $g_i(s)$. $\square$

Lemma 4.8. *As s tends to $-\infty$, $e^{-\beta^2 s} W$ tends to a finite positive limit.*

Proof. Letting $F = e^{-\beta^2 s} W$, we see that

$$F' = F \left(\sum_{j=1}^r X_j^2 - \beta^2 - \frac{\epsilon}{2} W^2 \right).$$

Near $s = -\infty$, the dominant terms in the bracket are $-\frac{\epsilon}{2} W^2$ and $(X_1 + \beta)(X_1 - \beta) \approx 2\beta(X_1 - \beta)$, which is negative since $\mathcal{H} < 1$ (Prop 3.10) implies that $X_1 < 1/\sqrt{d_1} = \beta$. So F is monotonic decreasing for large negative s .

The proposition is proved if we can show that F is bounded from above near $s = -\infty$.

For a sufficiently small $\delta > 0$ ($\delta < \frac{2}{3}\beta^2$ suffices for our purposes), we have $\sum_{j=1}^r X_j^2 - \frac{\epsilon}{2} W^2 > \beta^2 - \delta$ on some interval $(-\infty, s^*]$. Eqn.(1.8) then gives the inequality $(W^2)' \geq 2(\beta^2 - \delta)W^2$ and we deduce that

$$|W| \leq A_0 e^{(\beta^2 - \delta)s}$$

on such an interval. By choosing a smaller s^* if necessary, we can similarly ensure that

$$|X_1 - \beta| \leq A_1 e^{2(\beta^2 - \delta)s}, \quad |X_1 + \beta| \leq 2\beta + \delta,$$

$$|X_j(s)| \leq A_j e^{2(\beta^2 - \delta)s} \quad j \geq 2,$$

where A_j , $0 \leq j \leq r$ are appropriate positive constants. If we now integrate the equation for F over $[s, s^*]$ and apply the above estimates, we obtain an upper bound for $F(s)$. $\square$

Proposition 4.9. *u tends to a finite limit as t tends to 0.*

Proof. By integrating (1.10) we obtain

$$(4.10) \quad e^{u(0)} = (\text{positive constant}) \prod_{i=2}^r g_i(0)^{d_i} \left(\lim_{s \rightarrow -\infty} e^{-\beta^2 s} g_1 \right)^{d_1}.$$

The last limit, by (1.9), is $\lim_{s \rightarrow -\infty} \left(\sqrt{d_1 \lambda_1} (W/Y_1) e^{-\beta^2 s} \right)$, which is finite and positive by Lemma 4.8. $\square$

We shall next record some formulas that will be useful when we study the limiting values of the second and third derivatives of g_i . They are obtained from (4.6) by straightforward computation.

$$(4.11) \quad \ddot{g}_i = \frac{\lambda_i}{g_i Y_i^2} \left(X_i^2 + Y_i^2 - \sqrt{d_i} X_i + \frac{\epsilon}{2} d_i W^2 \right)$$

$$(4.12) \quad \frac{d^3 g_i}{dt^3} = \frac{\lambda_i}{g_i Y_i^2 W} \left(\frac{1}{\sqrt{d_i}} X_i (X_i^2 + Y_i^2) - 3X_i^2 - Y_i^2 + \sqrt{d_i} X_i \left(1 + \sum_{j=1}^r X_j^2 \right) + \frac{\epsilon}{2} W^2 (2\sqrt{d_i} X_i - d_i) \right)$$

We also need to obtain certain limits before proceeding further with smoothness considerations.

Lemma 4.13. *The limit $\rho := \lim_{s \rightarrow -\infty} \frac{Y_1^2 + \sum_{j=1}^r X_j^2 - 1}{W^2}$ exists and is finite.*

Proof. By the conservation law (1.12), we have

$$\begin{aligned} \frac{Y_1^2 + \sum_{j=1}^r X_j^2 - 1}{W^2} &= \frac{-\sum_{j=2}^r Y_j^2 + \epsilon u W^2 + (C - (n-1)\frac{\epsilon}{2})W^2}{W^2} \\ &= -\sum_{j=2}^r \left(\frac{Y_j}{W} \right)^2 + \epsilon u + C - (n-1)\frac{\epsilon}{2}. \end{aligned}$$

The last expression has a finite limit as s approaches $-\infty$ by Props 4.7 and 4.9 and our choice of trajectory. Note that the limit is negative since for our trajectories $\mathcal{L} < 0$ so $Y_1^2 + \sum_{j=1}^r X_j^2 - 1 < 0$. $\square$

Lemma 4.14. *The quantity $\frac{X_1 - \beta}{W^2}$ cannot tend to $-\infty$ as s tends to $-\infty$.*

Proof. As we saw in the proof of Lemma 4.8, $X_1 < \beta$, so $\frac{X_1 - \beta}{W^2} < 0$. Let us consider

$$(4.15) \quad \frac{(Y_1 - \hat{\beta})'}{2WW'} = \frac{Y_1}{2 \left(\sum_{j=1}^r X_j^2 - \frac{\epsilon}{2} W^2 \right)} \left(\sum_{j=2}^r \frac{X_j^2}{W^2} - \frac{\epsilon}{2} + \frac{X_1(X_1 - \beta)}{W^2} \right).$$

The term outside the bracket on the right-hand side tends to $\hat{\beta}/2\beta^2$, and the first term in the bracket tends to zero by Lemma 4.3 and Prop 4.7. So if $\frac{X_1 - \beta}{W^2}$ tends to $-\infty$, so does $\frac{(Y_1 - \hat{\beta})'}{(W^2)'}$, and hence, by L'Hôpital's rule, so does $\frac{Y_1 - \hat{\beta}}{W^2}$. But we also have

$$\frac{\sum_{j=1}^r X_j^2 + Y_1^2 - 1}{W^2} = \frac{(X_1 + \beta)(X_1 - \beta) + (Y_1 + \hat{\beta})(Y_1 - \hat{\beta}) + \sum_{j=2}^r X_j^2}{W^2}.$$

As s tends to $-\infty$, the left-hand side tends to a finite limit by Lemma 4.13 while the right-hand side tends to $-\infty$, a contradiction. $\square$

Lemma 4.16.

$$\lim_{s \rightarrow -\infty} \left(\frac{X_1 - \beta}{W^2} \right) = \frac{\beta\rho + \frac{\epsilon}{2}\beta(d_1 - 1)}{1 + \beta^2}.$$

Proof. We observe that $(X_1 - \beta)/W^2$ satisfies the differential equation

$$\left(\frac{X_1 - \beta}{W^2} \right)' = - \left(\frac{X_1 - \beta}{W^2} \right) \left(1 + \sum_{j=1}^r X_j^2 \right) + \frac{\beta}{W^2} \left(\sum_{j=1}^r X_j^2 + Y_1^2 - 1 \right) + \frac{\epsilon}{2} (\sqrt{d_1} - X_1) + \epsilon(X_1 - \beta).$$

By Lemma 4.13, as $s \rightarrow -\infty$, the term $\frac{\beta}{W^2} (\sum_{j=1}^r X_j^2 + Y_1^2 - 1)$ on the right-hand side tends to $\rho\beta$ while the sum of the last two terms tend to $\frac{\epsilon}{2}\beta(d_1 - 1)$. Now Lemma 4.1 shows that as s tends to

$-\infty$, $\frac{X_1 - \beta}{W^2}$ either tends to $-\infty$ or to the claimed value. But it cannot tend to $-\infty$ by Lemma 4.14, so we are done. $\square$

We now return to our analysis of the smoothness conditions.

Proposition 4.17. *$\ddot{g}_i(0)$ is finite for $i > 1$ and is zero if $i = 1$.*

Proof. For $i > 1$ we take the Y_i^2 factor in the denominator of (4.11) and distribute it into the bracket. It is now clear from Lemma 4.4 and Cor 2.11 that the right-hand side tends to a finite limit as t tends to zero.

If $i = 1$, using the conservation law (1.12) and the fact $g_1 Y_1 = \sqrt{d_1 \lambda_1} W$, we may rewrite (4.11) as

$$\ddot{g}_1 = \lambda_1 g_1 \left(\frac{1 - \sqrt{d_1} X_1}{d_1 \lambda_1 W^2} \right) + \frac{g_1}{d_1} \left(\epsilon u + C - (n-1) \frac{\epsilon}{2} \right) - \frac{g_1}{d_1} \sum_{j=2}^r \left(\frac{X_j^2}{Y_j^2} + 1 \right) \frac{Y_j^2}{W^2} + \frac{\epsilon}{2} \sqrt{d_1 \lambda_1} \frac{W}{Y_1}.$$

Since $g_1(0) = 0$, the first term on the right-hand side tends to 0 by Lemma 4.16. The second term of the right-hand side tends to zero by Prop 4.9. The third term on the right tends to zero by Lemma 4.3 and Prop 4.7. The last term on the right clearly tends to 0 since Y_1 tends to $\hat{\beta} \neq 0$. Hence $\ddot{g}_1(0) = 0$. $\square$

Similarly we can study the potential u . From the relation (1.10) we find that

$$(4.18) \quad \dot{u} = \frac{1}{W} \left(\left(\sum_{j=1}^r \sqrt{d_j} X_j \right) - 1 \right) = \sqrt{d_1} \left(\frac{X_1 - \beta}{W^2} \right) W + \sum_{i=2}^r \sqrt{d_i} \left(\frac{X_i}{Y_i^2} \right) \left(\frac{Y_i^2}{W^2} \right) W,$$

Hence $\dot{u}(0) = 0$ by Lemmas 4.16, 4.3 and Prop 4.7.

Upon differentiating (4.18) we obtain

$$(4.19) \quad \ddot{u} = \sum_{i=1}^r d_i \frac{\ddot{g}_i}{g_i} - \frac{\epsilon}{2} = \sum_{i=1}^r \frac{d_i \lambda_i}{g_i^2 Y_i^2} \left(X_i^2 + Y_i^2 - \sqrt{d_i} X_i + \frac{\epsilon}{2} d_i W^2 \right) - \frac{\epsilon}{2}.$$

In view of Props 4.7 and 4.17, it remains to see why $\ddot{g}_1/g_1$ tends to a finite value as $t \rightarrow 0$. This follows from the argument in the proof of Prop 4.17.

So our soliton (g, u) is of class C^2 . Finally, we will analyse the limit of third derivatives of g_i as t approaches 0.

If $i = 1$, we can rewrite (4.12) to obtain

$$\begin{aligned} \frac{d^3 g_1}{dt^3} &= \sqrt{\frac{\lambda_1}{d_1}} Y_1 \left(\frac{\epsilon}{2} \left(\frac{2\sqrt{d_1} X_1 - d_1}{Y_1^2} \right) + \sqrt{d_1} \left(\frac{X_1}{Y_1^2} \right) \sum_{j=2}^r X_j \frac{X_j}{Y_j^2} \left(\frac{Y_j}{W} \right)^2 \right. \\ &\quad \left. + \sqrt{d_1} \left(\frac{X_1}{Y_1^2} \right) \left(\frac{1 + X_1^2}{W^2} \right) + \frac{1}{W^2} \left(-\frac{3X_1^2}{Y_1^2} + \beta X_1 + \frac{\beta X_1^3}{Y_1^2} - 1 \right) \right). \end{aligned}$$

The first term within the big bracket on the right-hand side certainly tends to a finite limit and the second term tends to 0 by Lemma 4.3 and Prop 4.7. Now the analogous argument to that in the steady case (two paragraphs before the statement of Theorem 4.17 in [DW2]) with $\mathcal{L}$ replaced by W^2 shows that the third and fourth term tend to a finite limit.

If $i > 1$, using (1.3) in (4.12) and the initial conditions $Y_i(0) = 0$, we see that in order for the third derivatives to have 0 as a limit, it suffices to show that

$$\frac{1}{W^2} \left(-3 \frac{X_i^2}{Y_i^2} - 1 + \frac{X_i}{\sqrt{d_i}} \left(1 + \frac{X_i^2}{Y_i^2} \right) + \sqrt{d_i} \frac{X_i}{Y_i^2} \left(1 + \sum_{j=1}^r X_j^2 \right) + \frac{\epsilon}{2} \frac{W^2}{Y_i^2} (2\sqrt{d_i} X_i - d_i) \right)$$

has a finite limit as $s \rightarrow -\infty$. Again by Lemma 4.4 and Prop 4.7, it follows that $\frac{X_i}{W^2}$ and hence $\frac{X_i^2}{Y_i^2 W^2}$ have finite limits, so we are reduced to showing that

$$\frac{1}{W^2} \left(-\frac{1}{\sqrt{d_i}} + \frac{X_i}{Y_i^2} (1 + X_i^2) - \frac{\epsilon}{2} \sqrt{d_i} \frac{W^2}{Y_i^2} \right)$$

has a finite limit.

Now $1 + X_1^2 = 1 + \beta^2$ and $W/Y_i = \mu_i$ modulo terms which tend to a finite limit when divided by W^2 (for the second case we use L'Hopital's rule). So we just have to check that

$$Q_i := \frac{1}{W^2} \left(\frac{X_i}{Y_i^2} - \frac{\frac{1}{\sqrt{d_i}} + \frac{\epsilon}{2} \sqrt{d_i} \mu_i^2}{1 + \beta^2} \right)$$

has a finite limit.

Let $\tilde{\mu}_i := \frac{\frac{1}{\sqrt{d_i}} + \frac{\epsilon}{2} \sqrt{d_i} \mu_i^2}{1 + \beta^2}$. Proceeding as in the steady case, we find that Q_i satisfies the equation

$$\begin{aligned} Q_i' &= \left(-1 - 3 \sum_j X_j^2 + 2 \frac{X_i}{\sqrt{d_i}} + \epsilon W^2 \right) Q_i \\ &\quad + \left[\frac{\tilde{\mu}_i}{W^2} \left(-1 - \sum_{j=1}^r X_j^2 + 2 \frac{X_i}{\sqrt{d_i}} \right) + \frac{1}{W^2} \left(\frac{1}{\sqrt{d_i}} + \frac{\epsilon}{2} \frac{W^2}{Y_i^2} (\sqrt{d_i} + X_i) \right) \right]. \end{aligned}$$

The coefficient of Q_i on the right-hand side tends to $-1 - 3\beta^2$ as $s \rightarrow -\infty$. Using arguments similar to those above (cf. the arguments in the steady case three paragraphs before the statement of Theorem 4.17 in [DW2]), we can also check that the term in square brackets on the right tends to a finite positive limit. So the hypotheses of Lemma 4.1 are satisfied, and Q_i either tends to a finite limit or to $+\infty$ or $-\infty$. But one can also compute that

$$\frac{\left(\frac{X_i}{Y_i^2} - \tilde{\mu}_i \right)'}{(W^2)'} = \frac{\left(\frac{X_i}{Y_i^2} - \tilde{\mu}_i \right)}{W^2} \left(\frac{-(1 + \beta^2)}{2 \left(\sum_{j=1}^r X_j^2 - \frac{\epsilon}{2} W^2 \right)} \right) + R_i$$

where R_i tends to a finite limit. So if the limit of Q_i is infinite, L'Hôpital's rule gives a contradiction, as the term in the final bracket has a negative limit.

We have now shown that the metric is C^3 and so by the discussion on regularity near the beginning of §3 in [DW2], the soliton is smooth. To summarise we may now state the

Theorem 4.20. *Let $M_2, \dots, M_r$ ($r \geq 1$) be complete Einstein manifolds with positive scalar curvature. For $d_1 > 1$ there is an r -parameter family of smooth complete expanding gradient Ricci solitons on the trivial rank $d_1 + 1$ vector bundle over $M_2 \times \dots \times M_r$. $\square$*

Remark 4.21. Recall that C. Böhm proved in [B] that there is also an $r - 1$ -parameter family of complete Einstein metrics with negative scalar curvature on the above manifolds. These metrics correspond to trajectories which lie in the invariant submanifold $\{Q = 0, \mathcal{H} = 1\}$ and which converge to the point E_+ (cf Remark 3.12). When $r = 1$, the invariant submanifold is a curve, and this is precisely the hyperbolic trajectory mentioned in [Cetc], corresponding to the hyperbolic metric on $\mathbb{R}^{d_1+1}$. It follows easily from our equations that the mean curvature of the hypersurfaces tends to the constant $\sqrt{n\epsilon/2}$ as $t \rightarrow +\infty$ and the metric coefficients g_i^2 grow exponentially fast (compare Remark 3.30).

Our proof of Theorem 4.20, with appropriate minor modifications, then gives an alternative proof of Böhm's result. (In particular, since we are in the Einstein case, we no longer need to consider the third order derivatives in the regularity analysis.)

Finally, recall that the metrics of our steady solitons in [DW2] have non-negative Ricci curvature. The analogous fact in the expanding case is

Proposition 4.22. *The soliton potentials u in the examples in Theorem 4.20 are concave, indeed strictly concave off the zero section. Hence $\text{Ric}(g) + \frac{\epsilon}{2}g$ is positive semi-definite. In particular, $-u$ is subharmonic.*

Proof. It suffices to show that $\frac{\dot{u}}{g_i}u$ and $\ddot{u}$ are negative for $0 < t < +\infty$. The first fact follows from (1.11), (4.18), the positivity of W, X_i and Prop 3.10. To see the second, note that $\ddot{u} = (\mathcal{Q} + 1 - \mathcal{H})/W^2$ by (4.19) and consider the equation

$$(\mathcal{Q} + 1 - \mathcal{H})' = (\mathcal{Q} + 1 - \mathcal{H})(G - 1 - \epsilon W^2) + \mathcal{Q}G + \frac{\epsilon}{2}(\mathcal{H} - 1)W^2,$$

which follows from (3.5)-(3.6) and where $G = \sum_i X_i^2$. By Prop 3.10, on the right-hand side, the second factor of the first term and the second and third terms are all negative. So if $\mathcal{Q} + 1 - \mathcal{H} \geq 0$ at some s_0 , it has to be strictly decreasing on the left of s_0 . This contradicts the fact that $\mathcal{Q} + 1 - \mathcal{H}$ tends to 0 as $s \rightarrow -\infty$. $\square$
